

Phase 2: even a copula built for the $\chi_L > \chi_U$ structure recovers no material scheduling value: the mean field dominates

max single-seed gain 0.18%;
sampling noise across seeds

A. The copula ceiling Λ is at the noise floor
(upper-Fréchet sup: max single-seed gain 0.18%, ≈ 0 over seeds)

B. The copula DOES capture asymmetry
(Clayton edges Gaussian where dependence is heterogeneous)
