

Just move the compute to the cleanest grid.

That alone cuts worst-case carbon **4 to 10%** (18,000 to 46,000 tonnes CO2 a year).

Modelling how the grids correlate, on top of that, adds nothing.

about 0%

extra benefit from correlation
and copula models, so keep it simple

$M^* = 3$

how extreme an emergency must be
before robustness is worth it

0 of 17

real grids that ever get that
extreme, so robustness stays on the shelf

THE BOTTOM LINE

Ship the simple migration scheduler now. Skip the joint-covariance and copula modelling. Turn robustness on only if conditions get worse than any real grid has seen.
